Some More Architectural Questions

How do we document architectures?

The agile methods have deprecated design… or at least design documentation.
• If using agile, do we need to worry about architecture?
• What level of architectural documentation is needed / appropriate?

If architecture should be viewed from the system’s goals, how do we get those goals?
• How can we select architecture tradeoffs in light of business goals?

What is the future of architecture?
An Example Architecture

See wiki.sei.cmu.edu/sad/ for an example of a software architecture.
  • Adventure Builder – Software Architecture Document

Includes
  • use cases (4)
  • module views (5)
  • C&C views (3)
  • allocation views (2)

Problem Source

Adventure Builder Reference Application
• Adventure Builder is a fictitious company that sells adventure packages for vacationers over the Internet.

An adapted version of the Adventure Builder Reference application.
- developed in the context of the Java BluePrints program at Sun Microsystems
- functionality is easy to understand
- source code, documentation, and other artifacts are publicly available for download.
- Singh book on Web services (2004) explains the design and implementation of the application
Use Cases (UC1)

The user can visit the Adventure Builder Web site and browse the catalog of travel packages. Includes

- flights to specific destinations
- lodging options
- activities that can be purchased in advance

Activities include

- mountain biking
- fishing
- surfing classes
- hot air balloon tours
- scuba diving

The user can select transportation, accommodation, and various activities to build his/her own adventure trip.
Use Cases (UC2)

The user can place an order for a vacation package.

To process this order, the system has to interact with several external entities.

- A bank will approve the customer payment.
- Airline companies will provide the flights.
- Lodging providers will book the hotel rooms.
- Businesses that provide vacation activities will schedule the activities selected by the customer.
Use Cases (UC3)

After an order is placed, the user can return to check the status of his/her order.
- This is necessary because some interactions with external entities are processed in the background and may take hours or days to complete.
Use Cases (UC4)

The internal system periodically interacts with its business partners:
- transportation
- lodging
- activity providers

to update the catalog with the most recent offerings.
Use Cases (A Use Case Context Diagram)
Quality Attribute Scenario
Modifiability

A new business partner (airline, lodging, or activity provider) that uses its own web services interface is added to the system in no more than 10 person-days of effort for the implementation.

The business goal is easy integration with new business partners.
Quality Attribute Scenario
Performance

A user places an order for an adventure travel package to the Consumer Web site.

The user is notified on screen that the order has been successfully submitted and is being processed in less than five seconds.
Quality Attribute Scenario
Performance

Up to 500 users click to see the catalog of adventure packages following a random distribution over 1 minute
• the system is under normal operating conditions
• the maximal latency to serve the first page of content is under 5 seconds
• average latency for same is less than 2 seconds
Quality Attribute Scenario

Reliability

The Consumer Web site sent a purchase order request to the order processing center (OPC).

The OPC processed that request but didn’t reply to Consumer Web site within five seconds
• the Consumer Web site resends the request to the OPC

The OPC receives the duplicate request
• the consumer is not double-charged
• data remains in a consistent state
• the Consumer Web site is notified that the original request was successful

one hundred percent of the time
Quality Attribute Scenario
Security

Credit approval and payment processing are requested for a new order.

In one hundred percent of the cases
• the transaction is completed securely
• cannot be repudiated by either party

The business goals are to provide customers and business partners confidence in security and to meet contractual, legal, and regulatory obligations for secure credit transactions.
Quality Attribute Scenario
Security

The OPC experiences a flood of calls through the Web Service Broker endpoint that do not correspond to any current orders.

In one hundred percent of the times, the system
• detects the abnormal level of activity
• notifies the system administrator
• continues to service requests in a degraded mode
The Consumer Web site is available to the user 24x7.

If an instance of OPC application fails, the fault is detected
- the system administrator is notified in 30 seconds
- the system continues taking order requests
- another OPC instance is created
- data remains in consistent state

Rationale
Related views
Consumer Website

The web-based user interface of the Adventure Builder is implemented in this module:
- lets the user browse the catalog of travel packages
- place a new purchase order
- track the status of existing orders
- creates purchase orders based on user input and passes them to OpcApp for processing
- uses an implementation of the Model View Controller pattern called the Web Application Framework (waf)
  - model implemented using Entity beans
  - controller implemented using servlets
  - view is a collection of JSPs and static HTML pages
- part of the client-facing code is implemented using the GWT framework
Order Processing Center Application
OpcApp

The business logic of the Adventure Builder is implemented in this module.

- Accepting purchase order requests from the Consumer Website for processing by hosting the Purchase Order Web Service.
- Provide a mechanism for the Consumer Website to query the current status of a purchase order by hosting the Order Tracking Web Service.
- Communicate with external suppliers to process and maintain the status of a purchase order.
- Upon completion of processing a purchase order, send an email to the customer of its success or failure.
OPC Module Decomposition View (2)
Rationale

The choice of EJBs in the implementation, including session beans, message-driven beans and entity beans is based on:

- Developers are familiar with EJB development and component-based development.
- These highly modular EJB components promote reuse.

What Is An “Agile Method”?

A software engineering “methodology” that follows the Agile Manifesto?

A method that supports responding rapidly to changing requirements?
  - Mark Paulk

Does an agile method necessarily imply
  • Evolutionary / iterative / incremental development?
  • Empowerment / participation of the development team?
  • Active collaboration with the customer?
  • ...

Agile Manifesto

We are uncovering better ways of developing software by doing it and helping others do it. Through this work we have come to value:

**Individuals and interactions** over processes and tools
**Working software** over comprehensive documentation
**Customer collaboration** over contract negotiation
**Responding to change** over following a plan

That is, while there is value in the items on the right, we value the items on the left more.

Architecture in an Agile Context

The best teams may be self-organizing, but the best architectures still require technical skill, deep experience, and deep knowledge.

A focus on early and continuous release of software, where “working” is measured in terms of customer-facing features, leaves little time for addressing the kinds of cross-cutting concerns and infrastructure critical to a high-quality large-scale system.

The issue is not agile vs architecture but how to best blend agile and architecture…
Building the Foundation
Documentation and YAGNI

Expect the greatest agile friction from evaluation and documentation.

Technical documentation principle: write for the reader.
• No reader $\rightarrow$ no documentation

The Views and Beyond approach (Clements 2002)
- uses the architectural view as the “unit” of documentation
- prescribes producing a view if and only if it addresses substantial concerns of an important stakeholder community
- the view selection method prescribes producing the documentation in prioritized stages to satisfy the needs of the stakeholders who need it now
All good software-intensive architectures are agile.
- a successful architecture is resilient and loosely coupled
- composed of a core set of well-reasoned design decisions
- contains some “wiggle room” that allows modifications to be made and refactorings to be done

An effective agile process will allow the architecture to grow incrementally as the system is developed and matures.
- decomposability
- separation of concerns
- near-independence of the parts

The architecture should be visible and self-evident in the code
- make the design patterns, cross-cutting concerns, and other important decisions obvious, well communicated, and defended
- may, in turn, require documentation
- “socialize” the architecture
Tradeoff Advice

Large and complex system with relatively stable and well-understood requirements
• do a large amount of architecture work up front

Big projects with vague or unstable requirements
• quickly design a complete candidate architecture
• Cockburn’s Crystal Clear “walking skeleton”

Smaller projects with uncertain requirements,
• try to get agreement on the central patterns
Documenting Software Architectures

If it is not written down, it does not exist.
  • Philippe Kruchten

If you don’t have it in writing, I didn’t make a commitment.
  - mcp

(A lack of planning on your part does not constitute a crisis on my part.)
  - mcp

Architecture has to be communicated in a way to let its stakeholders use it properly to do their jobs.
Uses of Architecture Documentation

As a means of education
• introducing people to the system

As a primary vehicle for communication among stakeholders
• including the architect in the project’s future

As the basis for system analysis and construction
Notations

Informal notations
- general-purpose diagramming and editing tools and visual conventions

Semiformal notations
- a standardized notation that prescribes graphical elements and rules of construction, e.g., UML

Formal notations
- has a precise (usually mathematically based) semantics
- formal analysis of both syntax and semantics is possible
- generally referred to as architecture description languages
- the use of such notations is rare
Module Views

A module is an implementation unit that provides a coherent set of responsibilities.

The relations that modules have to one another include *is part of*, *depends on*, and *is a*.

It is unlikely that the documentation of any software architecture can be complete without at least one module view.
**Component-and-Connector Views**

Show elements that have some runtime presence
- processes, objects, clients, servers, and data stores

Include as elements the pathways of interaction
- communication links and protocols, information flows, and access to shared storage

Components have interfaces called ports.

Connectors have roles, which are its interfaces, defining the ways in which the connector may be used by components to carry out interaction.
Allocation Views

Describe the mapping of software units to elements of an environment in which the software is developed or in which it executes.

The relation in an allocation view is allocated to.

The usual goal of an allocation view is to compare
• the properties required by the software element with
• the properties provided by the environmental elements
to determine whether the allocation will be successful or not.
Architectures Are Abstractions

Cannot be seen in the low-level implementation details

Tools aggregate abstractions
  • not a panacea
  • no programming language construct for layer or connector or ...

Architecture reconstruction is an interpretive, interactive, iterative process

Workbench – open, integration framework
UML

The Unified Modeling Language (UML) is a visual language for specifying, constructing, and documenting the artifacts of systems.
- Object Management Group (OMG)
- UML 2.0 Infrastructure Specification

A model is a set of UML diagrams that represent various aspects of the software product.
• UML is the tool that we use to represent (model) the target software product

UML profiles
• specialized subsets of the notation for common subject areas
  - EJB profile for Enterprise JavaBeans
UML Diagrams
Applying UML

UML as sketch
• informal and incomplete diagrams (often hand drawn on whiteboards) created to explore difficult parts of the problem or solution space
• emphasized in agile modeling

UML as blueprint
• relatively detailed design diagrams used for reverse engineering or code generation

UML as programming language
• complete executable specification of a software system in UML
Monopoly Case Study (Larman)

Use cases aren’t always best for behavior requirements…
If someone wants the model maintained… redraw using a CASE tool. Who is going to use the updated model and why?
Monopoly Partial Domain Model

- Played-with: Die
  - faceValue

SSD for a PlayMonopolyGame Scenario
Documenting an Architecture

Case study of ~200KLOC open source product

Very little architectural documentation

Team reverse-engineered the architecture (2-3 person weeks of effort) and provided the architecture to the developers

- system could be characterized as poor quality architectural design (my opinion)

Reverse-Engineered Module Relationships in HDFS (Kazman 2016)
Documented Module Relationships in HDFS (Kazman 2016)
Value of Architecture Documentation

“Committers” did not need or value the architecture documentation.
- system was small enough to keep architectural details in their heads

“Outsiders” were promoted to “committers” more quickly using the architecture documentation.
- decentralization occurred
- developers looked at the documentation rather than asking one of the committers about the architecture

Committers were unwilling to maintain the architecture documentation.
- need to use tools to automatically extract and maintain architectural information
Architecturally Significant Requirements (ASRs)

Requirements documents
• most of what is in a requirements specification does not affect the architecture
• much of what is useful to an architect is not in even the best requirements document
• ASRs often derive from business goals in the development organization
• excavation and archaeology is required to dig ASRs from requirements documents

Interviewing Stakeholders

Architects often have good ideas what quality attributes are exhibited by similar systems and are reasonable.

Stakeholders often have no idea what quality attributes they want in a system.

Results of stakeholder interviews
• a list of architectural drivers
• a set of quality attribute scenarios that the stakeholders (as a group) prioritized
Quality Attribute Workshop

1) QAW Presentation and Introductions
2) Business/Mission Presentation
3) Architectural Plan Presentation
4) Identification of Architectural Drivers
5) Scenario Brainstorming
6) Scenario Consolidation
7) Scenario Prioritization
8) Scenario Refinement
Gathering ASRs by Understanding the Business Goals

Business goals are the reason for building a system.
- Often the precursor of requirements that may or may not be captured in a requirements specification

Business goals often lead to quality attribute requirements.
- Every quality attribute requirement should originate from some higher purpose that can be described in terms of added value

Business goals may directly affect the architecture without precipitating a quality attribute requirement at all.
Pedigreed Attribute eLicitation Method (PALM)

Day and a half workshop attended by architects and stakeholders who can speak to the business goals of the organizations involved
1) PALM overview presentation
2) Business drivers presentation
3) Architecture drivers presentation
4) Business goals elicitation
5) Identification of potential quality attributes from business goals
6) Assignment of pedigree to existing quality attribute drivers
7) Exercise conclusion
Utility Tree

Begins with the word “utility” as the root node.

List the major quality attributes that the system is required to exhibit.
  • under each quality attribute, record a specific refinement of that QA
  • under each refinement, record the appropriate ASRs (usually expressed as QA scenarios)

Evaluate against two criteria
  • the business value of the candidate ASR
  • the architectural impact of including it
    - must-have, important, nice-to-have
Tying the Methods Together

If you have a requirements process that gathers, identifies, and prioritizes ASRs, consider yourself lucky...

If nobody has captured the business goals behind the system you’re building, then a PALM exercise.

If you feel that important stakeholders have been overlooked, capture their concerns through interviews.
  • Quality Attribute Workshop

Building a utility tree is a good way to capture ASRs along with their prioritization.
Designing an Architecture

The building blocks for designing a software architecture:
• locating architecturally significant requirements
• capturing quality attribute requirements
• choosing, generating, tailoring, and analyzing design decisions for achieving those requirements

Now to pull the pieces together…
Attribute-Driven Design (ADD) Method

Produce a workable architecture quickly

Before beginning a design process, the requirements should (ideally) be known...

Requirements (changes) are continually arriving...

ADD can begin when a set of architecturally significant requirements is known.
Breadth vs Depth First

Personnel availability may dictate a refinement strategy.

Risk mitigation may dictate a refinement strategy.

Deferral of some functionality or quality attribute concerns may dictate a mixed approach.

All else being equal, a breadth-first refinement strategy is preferred because
• it allows you to apportion the most work to the most teams soonest
• allows for consideration of the interaction among the elements at the same level
Generate a Design Solution

Sources of design candidates—patterns, tactics, and checklists
• initial candidate design will likely be inspired by a pattern
• possibly augmented by one or more tactics
• consider the design checklists for the quality attributes

To the extent that the system you’re building is similar to others, it is likely that the solutions you choose will solve a collection of ASRs simultaneously…
Verify and Refine Requirements

Your design solution may not satisfy all the ASRs.

Backtrack – reconsider the design.

Unsatisfied ASRs may relate to

• A quality attribute requirement allocated to the parent element
• A functional responsibility of the parent element
• One or more constraints on the parent element
What Requirements Are Left?

Requirements assigned to element are satisfied...

Delegate to one of the children

Distribute among the children

Cannot be satisfied with the current design
  • backtrack
  • push back on the requirement
Done?

Terminate with a sketch of the architecture…
  • flesh out the architecture consistent with the overall design approaches laid out

Satisfy (contractual) specifications…

Exhaust design budget…

Terminating ADD and releasing the architecture are different decisions.
  • early architectural views can be usable
Architecture and Business

Perhaps the most important job of an architect is to be a fulcrum where business and technical decisions meet and interact…

What are the economic implications of an architectural decision?
Utility Response Curves

Each scenario’s stimulus-response pair provides some utility (value) to stakeholders.

The utility of different possible values for the response can be compared.

Absolute numbers are not necessary to compare alternatives…
  • human beings are better at comparative estimation.
Some Sample Utility-Response Curves
Best and Worst Cases

Best-case quality attribute level – that above which the stakeholders foresee no further utility

Worst-case quality attribute level – the minimum threshold above which a system must perform, otherwise it is of no value to the stakeholders

Current quality attribute level

Desired quality attribute level

Anchor the utility levels on a scale of 0-100 with the worst and best cases
Questions and Answers
